Computing Systems

Motivation

Why Scala?

Used by many modern concurrency frameworks

- Syntactic flexibility
- Programming models as Embedded Domain Specific Languages
- Many useful features

Safe language

- Automatic garbage collection
- Automatic bound checks
- No pointer arithmetic
- Static type safety

Java interoperability

- Compiled to Java bytecode
- Can use existing Java libraries
- Good interaction with Java's rich ecosystem
- Chosen by some Java-compatible frameworks

Executing Scala

Running with SBT

```
object SquareOf5 extends App {  
    def square(x: Int): Int = x * x  
    val s = square(5)  
    println(s"Result: $s")  
}
```

Call stack vs. object heap

where are values stored?

Concurrent threads:

do not share the call stack,
share the object heap,

```
object SquareOf5 extends App {  
    def square(x: Int): Int = x * x  
    val s = square(5)  
    println(s"Result: $s")  
}
```

Call stack vs. object heap

where are values stored?

Concurrent threads:

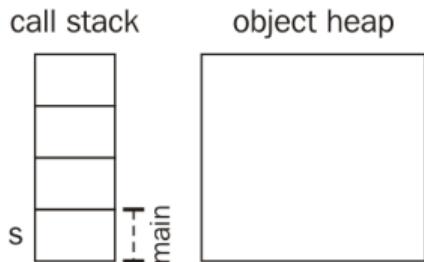

do not share the call stack,
share the object heap,

Local: SBT (practical lessons)

[in "Learning Concurrent Programming in Scala", pg. 19]

Scala in a nutshell

Creating a Printer class

```
class Printer(val greeting: String) {  
    def printMessage(): Unit =  
        println(greeting + "!")  
    def printNumber(x: Int): Unit = {  
        println("Number:" + x)  
    }  
}
```

One greeting parameter
Two methods

Creating a Printer class

```
class Printer(val greeting: String) {  
    def printMessage(): Unit =  
        println(greeting + " !")  
    def printNumber(x: Int): Unit = {  
        println("Number:" + x)  
    }  
}
```

Using the class

```
val printy = new Printer("Hi")  
// instantiate  
printy.printMessage() // ?  
printy.printNumber(5) // ?
```

```
object Test {  
    val Pi = 3.14  
}
```

Using the object

```
val x = Test.Pi * 5 * 5  
// no need to instantiate
```

Traits (similar to Java Interfaces)

```
trait Logging {  
    def log(s: String): Unit // just declared  
    def warn(s: String) = log("WARN:" + s)  
    def error(s: String) = log("ERROR:" + s)  
}  
  
class PrintLogging extends Logging {  
    def log(s: String) = println(s)  
}
```

Using traits

```
val x = new PrintLogging  
val y = new Logging {  
    def log(s:String): Unit =  
        println(s)  
}
```

Type parameters

```
class Pair[A,B](val fst: A, val snd: B)
```

Using Pair

```
val x: Pair[Int, String] =  
    new Pair(4, "a")  
val y = new Pair(2,5) //  
infer type
```

Lambdas (anonymous functions)

```
val twice_a: Int=>Int = (x:Int) => x*2
val twice_b = (x:Int) => x*2
val twice_c: Int=>Int = x => x*2
val twice_d: Int=>Int = _ * 2
```

Using lambdas

```
val x = twice_a(4)
```

Byname parameters (lazy)

```
def runTwice(body: =>Unit) = {  
    body  
    body  
}
```

Using Byname

```
runTwice { // prints "Hello" twice  
    println("Hello")  
}
```

“for” expressions and comprehension

```
for (i <- 0 until 10) println(i)
// equivalent to
0.until(10).foreach(i => println(i))

val negatives_a =
  for (i <- 0 until 10) yield -i
val negatives_b =
  (0 until 10).map(i => -1 * i)
```

“for” expressions and comprehension

```
for (i <- 0 until 10) println(i)
// equivalent to
0.until(10).foreach(i => println(i))

val negatives_a =
  for (i <- 0 until 10) yield -i
val negatives_b =
  (0 until 10).map(i => -1 * i)
```

```
val pairs_a =
  for (x <- 0 until 4;
       y <- 0 until 4) yield (x, y)
val pairs_b =
  (0 until 4).flatMap(x =>
    (0 until 4).map(y =>
      (x, y)))
```

Common collections:

Seq[T], List[T], Set[T], Map[K,V]

```
val msgs_a: Seq[String] =  
  Seq("Hello", "world!")  
  
val msgs_b: List[String] =  
  "Hello" :: "World" :: Nil  
  
val msgs_c: Set[String] =  
  Set("Hello", "world!")  
  
val msgs_d: Map[String, Int] =  
  Map("Hello" -> 5, "world!" -> 6)
```

String interpolation:

```
val number = 7  
val msg =  
  s"After $number comes ${number+1}!"
```

Pattern matching

```
val successors =  
  Map(1 -> 2, 2 -> 3, 3 -> 4)  
successors.get(5) match {  
  case Some(n) =>  
    println(s"Successor is: $n")  
  case None     =>  
    println("Could not find successor.")  
}
```

```
trait IntOrError  
case class MyInt(i: Int)  
  extends IntOrError  
case class MyError(e: String)  
  extends IntOrError  
  
//...  
def show(ie: IntOrError)  
  ie match {  
    case MyInt(i)    =>  
      println(s"Number: $i")  
    case MyError(e)  =>  
      println(s"Error: $e")  
  }  
}
```

Try-catch

```
trait IntOrError
case class MyInt(i:Int)      extends IntOrError
case class MyError(e:String) extends IntOrError

//...
def getInt(ie: IntOrError)
  ie match {
    case MyInt(i)    => i
    //case MyError(e) => ????
    // (match error if an error is found)
  }
}
```

```
def showInt(ie:IntOrError) =
  try {
    println(s"Int\uvalue:$ {getInt(i)}")
  } catch {
    case _: Throwable =>
      println("Got\u some\u error\u -\u probably\u not\u an\u int.")
  } finally {
    // always executes
    // (for side-effects, not
    // to return results)
    println("Done\u showing")
  }
```

Operator overloading

```
class Position(val x: Int, val y: Int) {  
    def +(that: Position) =  
        new Position(x + that.x, y + that.y)  
    def *(n: Int) =  
        new Position(x * n, y * n)  
}
```

Using operators

```
val p1 = new Position(3,4)  
val p2 = p1 + p1 * 2 //?
```

Package objects

File

src/main/scala/cp/lablessons/package.scala

```
package cp

package object lablessons {
    def log(msg: String): Unit =
        println(
            s"${Thread.currentThread.getName}: $msg"
        )
}
```

The `log` function is used throughout these lessons

Requires starting with
package cp.lablessons

- Stack and Heap
- Singleton objects
- Traits (similar to Java Interfaces)
- Type parameters
- Lambdas (anonymous functions)
- Byname parameters (lazy)
- “for” expressions
- “for” comprehension
- Scala collections and string interpolation
- Pattern matching
- Try-catch
- Operator overloading
- Package objects
