4. Modal Logic & Verification

José Proença System Verification (CC4084) 2024/2025

CISTER - U.Porto, Porto, Portugal

https://fm-dcc.github.io/sv2425

Syllabus

- Introduction to model-checking
- CCS: a simple language for concurrency
 - Syntax
 - Semantics
 - Equivalence
 - mCRL2: modelling
- Dynamic logic
 - Syntax
 - Semantics
 - Relation with equivalence
 - mCRL2: verification

- Timed Automata
 - Syntax
 - Semantics (composition, Zeno)
 - Equivalence
 - UPPAAL: modelling
- Temporal logics (LTL/CTL)
 - Syntax
 - Semantics
 - UPPAAL: verification
- Probabilistic and stochastic systems
 - Going probabilistic
 - UPPAAL: monte-carlo

Recall: What's in a logic?

A logic

A language

i.e. a collection of well-formed expressions to which meaning can be assigned.

A semantics

describing how language expressions are interpreted as statements about something.

A deductive system

i.e. a collection of rules to derive in a purely syntactic way facts and relationships among semantic objects described in the language.

Note

- a purely syntactic approach (up to the 1940's; the sacred form)
- a model theoretic approach (A. Tarski legacy)

- sentences
- models & satisfaction: $\mathcal{M} \models \phi$
- validity: $\models \phi$ (ϕ is satisfied in every possible structure)
- logical consequence: $\Phi \models \phi$ (ϕ is satisfied in every model of Φ)
- theory: ThΦ (set of logical consequences of a set of sentences Φ)

FC

Deductive systems \vdash

- sequents
- Hilbert systems
- natural deduction
- tableaux systems
- resolution
-

- derivation and proof
- deductive consequence: $\Phi \vdash \phi$
- theorem: $\vdash \phi$

System Verification 2024/25 @ FCUP

• A deductive system \vdash is sound wrt a semantics \models if for all sentences ϕ

$$\vdash \phi \implies \models \phi$$

(every theorem is valid)

• ··· complete ...

$$\models \phi \implies \vdash \phi$$

(every valid sentence is a theorem)

For logics with negation and a conjunction operator

- A sentence ϕ is refutable if $\neg \phi$ is a theorem (i.e. $\vdash \neg \phi$)
- A set of sentences Φ is refutable if some finite conjunction of elements in Φ is refutable
- ϕ or Φ is consistent if it is not refutable.

$\mathcal{M} \models \phi$

- Propositional logic (logic of uninterpreted assertions; models are truth assignments)
- Equational logic (formalises equational reasoning; models are algebras)
- First-order logic (logic of predicates and quatification over structures; models are relational structures)
- Modal logics
- · ...

Modal Logic

Over the years modal logic has been applied in many different ways. It has been used as a tool for reasoning about time, beliefs, computational systems, necessity and possibility, and much else besides.

These applications, though diverse, have something important in common: the key ideas they employ (flows of time, relations between epistemic alternatives, transitions between computational states, networks of possible worlds) can all be represented as simple graph-like structures.

Modal logics are

- tools to talk about relational, or graph-like structures.
- fragments of classical ones, with restricted forms of quantification ...
- ... which tend to be decidable and described in a pointfree notations.

Syntax

 $\phi ::= p \mid \text{true} \mid \text{false} \mid \neg \phi \mid \phi_1 \land \phi_2 \mid \phi_1 \rightarrow \phi_2 \mid \langle \alpha \rangle \phi \mid [\alpha] \phi$ where $p \in \text{PROP}$ and $\alpha \in \text{ACT}$

Disjunction (\lor) and equivalence (\leftrightarrow) are defined by abbreviation. The *signature* of the basic modal language is determined by sets:

- PROP of propositional symbols (typically assumed to be denumerably infinite) and
- ACT of structured actions (or programs), also called modality symbols.

Syntax

$\phi \ ::= \ \mathbf{p} \ | \ \operatorname{true} \ | \ \operatorname{false} \ | \ \neg \phi \ | \ \phi_1 \wedge \phi_2 \ | \ \phi_1 \to \phi_2 \ | \ \langle \alpha \rangle \phi \ | \ [\alpha] \phi$

where $p \in \mathsf{PROP}$ and $\alpha \in \mathsf{ACT}$

Ex. 4.1: Interpreting formulas

- (*drinkCoffee*) *energetic*: I will now drink coffee and will be in an energetic state
- [drink] ¬thirsty: If I drink anything now, I will not be in a thirsty state

Syntax

 $\phi ::= \mathbf{p} \mid \mathsf{true} \mid \mathsf{false} \mid \neg \phi \mid \phi_1 \land \phi_2 \mid \phi_1 \rightarrow \phi_2 \mid \langle \alpha \rangle \phi \mid [\alpha] \phi$

where $p \in \mathsf{PROP}$ and $\alpha \in \mathsf{ACT}$

Ex. 4.1: Interpreting formulas

- (*drinkCoffee*) *energetic*: I will now drink coffee and will be in an energetic state
- [drink] ¬thirsty: If I drink anything now, I will not be in a thirsty state
- [something*] [pressCoffee] (getCoffee) true: If do something any number of times, and then I press the coffee button, then I will get my coffee – and that's it.

Notes

- if there is only one modality in the signature (i.e., ACT is a singleton), write simply $\Diamond\phi$ and $\Box\phi$
- the language has some redundancy: in particular modal connectives are dual (as quantifiers are in first-order logic): [α] φ is equivalent to ¬⟨α⟩ ¬φ

Example

Models as LTSs over Act.

ACT = Act (sets of actions)

 $\langle a \rangle \, \phi$ can be read as "it must observe a, and ϕ must hold after that."

 $[a] \phi$ can be read as "if it observes a, then ϕ must hold after that."

Semantics

$$\mathcal{M}, s \models \phi$$
 – what does it mean?

Model definition

A model for the language is a pair $\mathcal{M}=\langle \mathcal{L},V
angle$, where

- $\mathcal{L} = \langle S, ACT, \longrightarrow \rangle$ is an LTS:
 - *S* is a non-empty set of states (or points)
 - ACT are the labels consisting of (structured) action symbols (or modality symbols)
 - $\longrightarrow \subseteq S \times ACT \times S$ is the transition relation
- $V : \mathsf{PROP} \longrightarrow \mathcal{P}(S)$ is a valuation.

When ACT = 1

- $\Diamond \phi$ and $\Box \phi$ instead of $\langle \cdot \rangle \phi$ and $[\cdot] \phi$
- $\mathcal{L} = \langle S, \longrightarrow \rangle$ instead of
 - $\mathcal{L} = \langle S, \mathsf{ACT}, \longrightarrow \rangle$
- $\longrightarrow \subseteq S \times S$ instead of $\longrightarrow \subseteq S \times ACT \times S$

Semantics

Safistaction: for a model \mathcal{M} and a state s

$\mathcal{M}, s \models true$		
$\mathcal{M}, s \not\models false$		
$\mathcal{M}, s \models p$	iff	$s \in V(p)$
$\mathcal{M}, \boldsymbol{s} \models \neg \phi$	iff	$\mathcal{M}, \boldsymbol{s} \not\models \phi$
$\mathcal{M}, \boldsymbol{s} \models \phi_1 \land \phi_2$	iff	$\mathcal{M}, s \models \phi_1$ and $\mathcal{M}, s \models \phi_2$
$\mathcal{M}, \boldsymbol{s} \models \phi_1 \rightarrow \phi_2$	iff	$\mathcal{M}, s \not\models \phi_1 \ ext{or} \ \mathcal{M}, s \models \phi_2$
$\mathcal{M}, \boldsymbol{s} \models \langle \alpha \rangle \phi$	iff	there exists $v \in S$ st $s \xrightarrow{\alpha} v$ a
$\mathcal{M}, \boldsymbol{s} \models [\alpha] \phi$	iff	for all $v \in S$ st $s \xrightarrow{\alpha} v$ and \mathcal{N}

 $s \xrightarrow{\alpha} v$ and $\mathcal{M}, v \models \phi$

v and $\mathcal{M}, v \models \phi$

Satisfaction

A formula ϕ is

- satisfiable in a model ${\mathcal M}$ if it is satisfied at some point of ${\mathcal M}$
- globally satisfied in \mathcal{M} $(\mathcal{M} \models \phi)$ if it is satisfied at all points in \mathcal{M}
- valid ($\models \phi$) if it is globally satisfied in all models
- a semantic consequence of a set of formulas Γ ($\Gamma \models \phi$) if for all models \mathcal{M} and all points s, if $\mathcal{M}, s \models \Gamma$ then $\mathcal{M}, s \models \phi$

Process logic (Hennessy-Milner logic)

- PROP = \emptyset (hence $V = \emptyset$)
- S = P is a set states in a labelled transition system, typically process terms
- structured actions are built by the grammar $K := a \in Act \mid K + K$
- the underlying LTS is given by $\mathcal{L} = \langle \mathcal{P}, Act, \{ \langle p, a, p' \rangle \mid a \in Act \} \rangle$

Satisfaction is abbreviated as

$$p \models \langle K \rangle \phi \qquad \text{iff} \quad \exists_{q \in \{p' \mid p \xrightarrow{a} p' \land a \in K\}} \cdot q \models \phi$$
$$p \models [K] \phi \qquad \text{iff} \quad \forall_{q \in \{p' \mid p \xrightarrow{a} p' \land a \in K\}} \cdot q \models \phi$$

System Verification 2024/25 @ FCUP

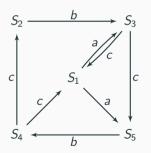

Specific modal logic: Process logic

Process Logic Syntax (Hennessy-Milner Logic)

 $\phi ::= \text{true} \mid \text{false} \mid \neg \phi \mid \phi_1 \land \phi_2 \mid \phi_1 \to \phi_2 \mid \langle \mathsf{K} \rangle \phi \mid [\mathsf{K}] \phi$

where $K := a \in Act \mid K + K$

Ex. 4.2: Prove:

- 1. $S_1 \models [a+b+c](\langle b+c \rangle \text{ true})$
- 2. $S_2 \models [a] (\langle b \rangle \operatorname{true} \land \langle c \rangle \operatorname{true})$
- 3. $S_1 \not\models [a] (\langle b \rangle \operatorname{true} \land \langle c \rangle \operatorname{true})$
- 4. $S_2 \models [b] [c] (\langle a \rangle \operatorname{true} \lor \langle b \rangle \operatorname{true})$
- 5. $S_1 \models [b] [c] (\langle a \rangle \operatorname{true} \lor \langle b \rangle \operatorname{true})$
- 6. $S_1 \not\models [a + b] \langle b + c \rangle (\langle a \rangle \text{ true})$

(P, <) a strict partial order with infimum 0 I.e., $P = \{0, a, b, c, ...\},$ $a \rightarrow b$ means a < b, a < b and b < c implies a < c0 < x, for any $x \neq 0$ there are no loops some elements may not be comparable

- $P, x \models \Box false$ if x is a maximal element of P
- $P, 0 \models \Diamond \square false$ iff ...
- $P, 0 \models \Box \Diamond \Box$ false iff ...

Temporal logic

- ⟨T, <⟩ where T is a set of time points (instants, execution states , ...) and < is the earlier than relation on T.
- Thus, $\Box \varphi$ (respectively, $\Diamond \varphi$) means that φ holds in all (respectively, some) time points.

Epistemic logic (J. Hintikka, 1962)

- W is a set of agents
- $\alpha \models [K_i] \phi$ means that agent *i* always knows that ϕ is true.
- $\alpha \models \langle K_i \rangle \phi$ means that agent *i* can reach a state where he knows ϕ .
- $\alpha \models (\neg[K_i] \phi) \land (\neg[K_i] \neg \phi)$ means that agent *i* does not know whether ϕ is true or not.

Many variations exist, modelling knowledge and believes, knowledge of who knows what, distributed knowledge, etc.

Deontic logic (G.H. von Wright, 1951)

- Obligations and permissions: must and can do.
- $\alpha \models \Box \phi$ means ϕ is obligatory.
- $\alpha \models \Diamond \phi$ means ϕ is a possibility.

Each logic accepts a different set of *principles* or *rules* (with variations), that makes their interpretation different.

Exercise

Ex. 4.3: Express the properties in Process Logic

- inevitability of a:
- progress (can act):
- deadlock or termination (is stuck):

Ex. 4.4: What does this mean?

1. $\langle - \rangle$ false

2. [-] true

"-" stands for $\sum_{a \in Act} a$, and "-x" abbreviates $\sum_{a \notin Act} a$

Recall syntax

$$\phi ::= true$$

$$| false$$

$$| \neg \phi$$

$$| \phi_1 \land \phi_2$$

$$| \phi_1 \rightarrow \phi_2$$

$$| \langle K \rangle \phi$$

$$| [K] \phi$$

where $K := a \mid K + K$

Exercise

Ex. 4.3: Express the properties in Process Logic • inevitability of *a*: $\langle - \rangle$ true $\wedge [-a]$ false progress (can act): deadlock or termination (is stuck): Ex. 4.4: What does this mean? 1. $\langle - \rangle$ false 2. [-] true "-" stands for $\sum_{a \in Act} a$, and "-x" abbreviates $\sum_{a \notin Act} a$

Recall syntax

ϕ	::=	true
		false
		$\neg \phi$
		$\phi_1 \wedge \phi_2$
		$\phi_1 \to \phi_2$
		$\langle \mathbf{K} \rangle \phi$
		$[K]\phi$

where $K := a \mid K + K$

Ex. 4.5: Coffee-machine

- 1. The user can have tea or coffee.
- 2. The user can have tea but not coffee.
- 3. The user can have tea after having 2 consecutive coffees.

Ex. 4.6: *a*'s and *b*'s

- 1. It is possible to do a after 3 b's, but not more than 1 a.
- 2. It must be possible to do a after [doing a and then b].
- 3. After doing a and then b, it is not possible to do a.

FC

Ex. 4.7: Taxi network

- $\phi_0 = \ln a \ taxi$ network, a car can collect a passenger or be allocated by the Central to a pending service
- $\phi_1 =$ This applies only to cars already on-service
- $\phi_2 = If$ a car is allocated to a service, it must first collect the passenger and then plan the route
- $\phi_3 = On$ detecting an emergency the taxi becomes inactive
- $\phi_4 = A$ car on-service is not inactive

Process Logic with regular expressions

 $\phi ::= \mathsf{true} \mid \mathsf{false} \mid \neg \phi \mid \phi_1 \land \phi_2 \mid \phi_1 \to \phi_2 \mid \langle \alpha \rangle \phi \mid [\alpha] \phi$

where $\alpha \in ACT$ are structured actions over a set Act:

 $\alpha := \mathbf{a} \in \mathbf{Act} \mid \alpha; \alpha \mid \alpha + \alpha \mid \alpha^*$

More expressive than Process Logic. Used by mCRL2.

System Verification 2024/25 @ FCUP

Process Logic with regular expressions

 $\phi ::= \mathsf{true} \mid \mathsf{false} \mid \neg \phi \mid \phi_1 \land \phi_2 \mid \phi_1 \to \phi_2 \mid \langle \alpha \rangle \phi \mid [\alpha] \phi$

where $\alpha \in ACT$ are structured actions over a set Act:

 $\alpha := \mathbf{a} \in \mathbf{Act} \mid \alpha; \alpha \mid \alpha + \alpha \mid \alpha^*$

Examples

- " $\langle a; b; c \rangle$ true" means " $\langle a \rangle \langle b \rangle \langle c \rangle$ true"
- "[*a*; *b*; *c*] false" means "[*a*][*b*][*c*] false"
- " $\langle a^*; b \rangle$ true" means that b can be taken after some number of a's.
- " $\langle -^*; a \rangle$ true" means that a can eventually be taken
- " $[-^*]\langle a+b\rangle$ true" means it is always possible to do a or b

Exercises

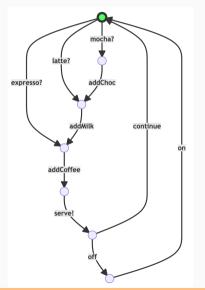

Ex. 4.8: What does this mean?

- $\langle -^*; serve! \rangle$ true
- [-*; (addChoc + addMilk); serve!] false
- [-*; addCoffee] (serve!) true
- $\langle \rangle$ true
- $[-^*]\langle \rangle$ true
- $[-^*; a] \langle b \rangle$ true
- $[-^*; send] \langle (-send)^*; recv \rangle$ true

Exercises

Ex. 4.9: Express using logic

- 1. The user can only have coffee after the coffee button is pressed.
- 2. The used must have coffee after the coffee button is pressed.
- 3. It is always possible to turn off the coffee machine.
- 4. It is always possible to reach a state where the coffee machine can be turned off.
- 5. It is never possible to add chocolate right after pressing the *latte button*.

mCRL2 Tools

Slides 3: https://fm-dcc.github.io/sv2425/slides/3-mcrl2.pdf

Bisimulation and modal equivalence

Definition

Given two models $\mathcal{M} = \langle \mathcal{L}, V \rangle$ and $\mathcal{M}' = \langle \mathcal{L}', V' \rangle$, a bisimulation of \mathcal{L} and \mathcal{L}' is also a bisimulation of \mathcal{M} and \mathcal{M}' if,

whenever s R s', then V(s) = V'(s')

System Verification 2024/25 @ FCUP

Lemma (invariance: bisimulation implies modal equivalence) Given two models \mathcal{M} and \mathcal{M}' , and a bisimulation R between their states:

if two states s, s' are related by R (i.e. sRs'), then s, s' satisfy the same basic modal formulas. (i.e., for all ϕ : $\mathcal{M}, s \models \phi \Leftrightarrow \mathcal{M}', s' \models \phi$)

Hence

Given 2 models ${\mathcal M}$ and ${\mathcal M}',$ if you can find ϕ such that

 $\mathcal{M} \models \phi \text{ and } \mathcal{M}' \not\models \phi$

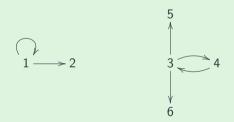

(or vice-versa) then they are NOT bisimilar.

System Verification 2024/25 @ FCUP

Ex. 4.10: Bisimilarity and modal equivalence

Consider the following transition systems:

Give a modal formula that can be satisfied at point 1 but not at 3.

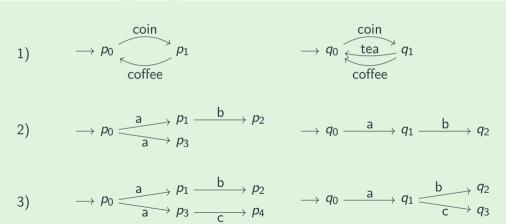

System Verification 2024/25 @ FCUP

Bisimulation and modal equivalence

Exercise

Ex. 4.11: Find distinguishing modal formula

Bisimulation and modal equivalence

Richer modal logics

Richer modal logics

can be obtained in different ways, e.g.

- axiomatic extensions
- introducing more complex satisfaction relations
- support novel semantic capabilities
- • • •

Examples

- richer temporal logics
- hybrid logic
- modal µ-calculus

Until and Since

$\mathcal{M}, \boldsymbol{s} \models \phi \mathcal{U} \psi$	iff	there exists r st $s \leq r$ and $\mathcal{M}, r \models \psi$, and
		for all t st $s \leq t < r$, one has $\mathcal{M}, t \models \phi$
$\mathcal{M}, \mathbf{s} \models \phi \mathcal{S} \psi$	iff	there exists r st $r \leq s$ and $\mathcal{M}, r \models \psi$, and
		for all t st $r < t \leq s$, one has $\mathcal{M}, t \models \phi$

- Defined for temporal frames $\langle T, \rangle$ (transitive, asymmetric).
- note the $\exists \forall$ qualification pattern: these operators are neither diamonds nor boxes.
- More general definition for other frames it becomes more expressive than modal logics.

Temporal logics - rewrite using \mathcal{U}

- $\Diamond \psi =$ $\Box \psi =$

Temporal logics - rewrite using ${\cal U}$

- $\Diamond \psi = \operatorname{tt} \mathcal{U} \psi$
- $\Box \psi =$

Temporal logics - rewrite using ${\cal U}$

- $\Diamond \psi = \operatorname{tt} \mathcal{U} \psi$
- $\Box \psi = \neg (\Diamond \neg \psi) = \neg (tt \mathcal{U} \neg \psi)$

Linear temporal logic (LTL)

$$\phi := \mathsf{true} \mid p \mid \phi_1 \land \phi_2 \mid \neg \phi \mid \bigcirc \phi \mid \phi_1 \, \mathcal{U} \, \phi_2$$

mutual exclusion	$\Box(\neg c_1 \lor \neg c_2)$
liveness	$\Box \Diamond c_1 \land \Box \Diamond c_2$
starvation freedom	$(\Box\Diamond w_1 \rightarrow \Box\Diamond c_1) \land (\Box\Diamond w_1 \rightarrow \Box\Diamond c_1)$
progress	$\Box(w_1 \to \Diamond c_1)$
weak fairness	$\bigcirc \Box w_1 \rightarrow \Box \diamondsuit c_1$
eventually forever	$\bigcirc \Box w_1$

- First temporal logic to reason about reactive systems [Pnueli, 1977]
- Formulas are interpreted over execution paths
- Express linear-time properties

Computational tree logic (CTL, CTL*)

FC

state formulas to express properties of a state:

$$\Phi := \mathsf{true} \mid \Phi \land \Phi \mid \neg \Phi \mid \exists \psi \mid \forall \psi$$

path formulas to express properties of a path:

 $\psi := \bigcirc \Phi \mid \Phi \, \mathcal{U} \, \Psi$

mutual exclusion	$\forall \Box (\neg c_1 \lor \neg c_2)$
liveness	$\forall \Box \forall \Diamond c_1 \land \forall \Box \forall \Diamond c_2$
order	$\forall \Box (c_1 \lor \forall \bigcirc c_2)$

- Branching time structure encode transitive, irreflexive but not necessarily linear flows of time
- flows are trees: past linear; branching future

Motivation

Add the possibility of naming points and reason about their identity

Compare:

$$\Diamond(r \wedge p) \land \Diamond(r \wedge q) \rightarrow \Diamond(p \wedge q)$$

with

$$\Diamond(i \wedge p) \land \Diamond(i \wedge q) \rightarrow \Diamond(p \wedge q)$$

for $i \in NOM$ (a nominal)

Syntax

$$\phi ::= \ldots \mid p \mid \langle \alpha \rangle \phi \mid [\alpha] \phi \mid i \mid @_i \phi$$

where $p \in \mathsf{PROP}$ and $\alpha \in \mathsf{ACT}$ and $i \in \mathsf{NOM}$

Nominals *i*

- Are special propositional symbols that hold exactly on one state (the state they name)
- In a model the valuation V is extended from

$$V : \mathsf{PROP} \longrightarrow \mathcal{P}(S)$$

to

$$V : \mathsf{PROP} \longrightarrow \mathcal{P}(S) \text{ and } V : \mathsf{NOM} \longrightarrow S$$

where NOM is the set of nominals in the model

• Satisfaction:

$$\mathcal{M}, s \models i$$
 iff $s = V(i)$

Hybrid logic

The $@_i$ operator

- $\mathcal{M}, s \models \mathsf{true}$ \mathcal{M} , $s \not\models \mathsf{false}$ $\mathcal{M}, s \models p$ $\mathcal{M}, \mathbf{s} \models \neg \phi$ \mathcal{M} , $\boldsymbol{s} \models \phi_1 \land \phi_2$ $\mathcal{M}, \mathbf{s} \models \phi_1 \rightarrow \phi_2$ $\mathcal{M}, \mathbf{s} \models \langle \alpha \rangle \phi$ $\mathcal{M}, \mathbf{s} \models [\alpha] \phi$
- $\mathcal{M}, \mathbf{s} \models \mathbf{0}_i \phi$

System Verification 2024/25 @ FCUP

- $\mathsf{iff} \quad s \in V(p)$
- iff $\mathcal{M}, \boldsymbol{s} \not\models \phi$
- $\mathsf{iff} \quad \mathcal{M}, \pmb{s} \models \phi_1 \; \; \mathsf{and} \; \; \mathcal{M}, \pmb{s} \models \phi_2$
- $\mathsf{iff} \quad \mathcal{M}, s \not\models \phi_1 \; \; \mathsf{or} \; \; \mathcal{M}, s \models \phi_2$
- $\text{iff} \quad \text{there exists } v \in S \text{ st } s \xrightarrow{\alpha} v \text{ and } \mathcal{M}, v \models \phi \\$
- $\text{iff} \quad \text{for all } v \in S \text{ st } s \xrightarrow{\alpha} v \text{ and } \mathcal{M}, v \models \phi \\$
- iff $\mathcal{M}, u \models \phi$ and u = V(i)
 - [u is the state denoted by i]

Richer modal logics

Summing up

- basic hybrid logic is a simple notation for capturing the bisimulation-invariant fragment of first-order logic with constants and equality, i.e., a mechanism for equality reasoning in propositional modal logic.
- comes cheap: up to a polynomial, the complexity of the resulting decision problem is no worse than for the basic modal language
